Scope
This guideline describes the care objectives for the prevention, diagnosis and management of diabetes mellitus (DM) in non-pregnant adults. It focuses on the approaches and systems that are ideally in place to improve care for the majority of patients the majority of the time.

Diagnostic Code: 250 – Diabetes mellitus

Prevention and Risk Factors
Safe and effective therapies for the prevention of type 1 DM have not yet been identified. The risk for developing type 1 DM is influenced by family history of type 1 DM and other autoimmune diseases.

A large proportion of type 2 DM can be prevented using lifestyle modification and/or pharmacologic intervention. Lifestyle modification is particularly important for persons considered at high-risk, and pharmacologic therapy with metformin or acarbose can also be considered for patients with impaired glucose tolerance (IGT). Risk factors for type 2 DM include but are not limited to: obesity; age ≥ 40 years; close relative with type 2 DM; member of a high risk population (Aboriginal, Hispanic, South Asian, Asian, or African descent); history of IGT or impaired fasting glucose (IFG) and other conditions associated with insulin resistance (e.g. dyslipidemia, hypertension, abdominal obesity, vascular disease, schizophrenia and use of antipsychotic medications).

Diagnosis
The classic diagnostic symptoms for DM are polyuria, polydipsia, and unexplained weight loss with a “casual”* plasma glucose (PG) ≥ 11.1 mmol/L. In the absence of classic symptoms, a fasting† plasma glucose (FPG) is the recommended initial test in the diagnosis of diabetes. Glycosylated hemoglobin (A1C) has been proposed as a diagnostic test for type 2 diabetes; however, has not universally been adopted. See Appendix A Screening Algorithm for Type 2 DM in Adults.

Lifestyle Management of DM*

Healthy Living
• Encourage a long-term healthy diet, recognizing diverse diets and needs.
• Calculate and optimize patient’s BMI (mass in kilograms/height in metres²)
  Target BMI: 18.5-24.9 kg/m²
  Note that desirable BMI range may be lower for certain populations, (e.g. Asian, Pacific).
• Measure and optimize patient’s waist circumference (WC).
  Targets for WC: M ≤ 94 cm; F ≤ 80 cm (Europid, Sub-Saharan African, Eastern Mediterranean and Middle Eastern); M ≤ 90 cm; F ≤ 80 cm (South Asian, Chinese, Japanese, South and Central American)⁶.
• Encourage aerobic exercise (30 min/day) and resistance exercise (i.e. weights) 3 sessions/week. Aerobic exercise and/or resistance training may also benefit elderly people with type 2 DM and can be recommended if not contraindicated. Consider an ECG stress test for previously sedentary people with additional risk factors for CVD who wish to undertake exercise more vigorous than brisk walking.
• At each visit encourage patient to stop smoking; provide support as needed.
**Self-Management**

- Educate patients regarding basic clinical management measurements such as blood glucose, glycosylated hemoglobin (A1C), BP (blood pressure), and lipid profile. Encourage patients to accept responsibility for the care of their DM and develop a mutually acceptable management plan, including an identified primary care provider and individualized self-monitoring of blood glucose (SMBG). See Controversies in Care: SMBG.
- Consider referral to a Diabetes education clinic.

*See Patient Education and Resources; for practitioners see www.primaryhealthcarebc.ca/phc/gpsc_initiatives.html*

**Management of Hyperglycemia and Hypoglycemia**

- Focus is on achieving target A1C levels and on minimizing symptomatic hyper- and hypoglycemia.

**Hyperglycemia**

Please refer to Appendix B for the Management of Hyperglycemia in type 2 DM, including details on when to initiate oral hypoglycemic medications or insulin without a 2-3 month trial of lifestyle modifications alone.

Appendix C: Antidiabetic Agents and Adjunctive Agents for Use in Type 2 DM

**Appendix D: Insulin Therapeutic Considerations and Availability**

**Hypoglycemia**

- Hypoglycemia can be serious complication of therapy. Consider less stringent glycemic targets in patients at risk.
- **Risk factors:** Prior episode of severe hypoglycemia, long-term DM, current low A1C (<6.0%), autonomic neuropathy, hypoglycemia unawareness, current treatment with insulin, and being elderly. Severe hypoglycemia is less common in persons with type 2 DM but the elderly and those on insulin or secretagogues are more vulnerable.
- **Prevention:** Educate patients and families about prevention, detection and treatment of hypoglycemia. See Patient Education and Resources.
- **To reduce the risk of hypoglycemia:** increase the frequency of SMBG (including episodic assessment during sleeping hours), make glycemic targets less stringent, and consider multiple insulin injections. **Treatment:** See Appendix E: Treatment of Hypoglycemia.

**Preventing complications and comorbidities of DM**

Healthy elderly people with DM may be treated to achieve the same targets as younger people, e.g. glucose control, BP, and lipids. Consider more conservative targets in people with multiple comorbidities, a high level of functional dependency, or limited life expectancy.

**Blood Pressure**

- BP control is a priority; measure and record at diagnosis and regularly thereafter: optimize to ≤130/80.7
- If lifestyle modification is not sufficient, choose from the following first-line agents: a thiazide diuretic, ACEI/ARB, cardioselective B-blocker.

**Blood Glucose: Long-term control**

Studies suggest there is a long-term “legacy” benefit of glucose lowering early in the course of type 1 & 2 DM.8,9
- Measure glycosylated hemoglobin (A1C) every three months to ensure that glycemic goals are being met or maintained. Target for most patients A1C ≤7.0% (See Controversies in Care).
- **Consider testing every 6 months if treatment and lifestyle remains stable and if targets have been consistently met.**
- Focus on minimizing symptomatic hypo- and hyperglycemia, in addition to A1C levels.

**Blood Glucose: SMBG**

- Reinforce patient's responsibility for regular monitoring as appropriate; ensure patients can use glucose meter, interpret results and modify treatment as needed. See Controversies in Care.
- Develop a blood glucose-monitoring schedule with patient and review records. SMBG is more important
when using a drug that can cause hypoglycemia. Targets for most patients: Pre-meal = 4.0 – 7.0 mmol/L; 2h Post-meal = 5.0 – 10.0 mmol/L (more lenient targets can be used in patients with history of hypoglycemia or the elderly).

- Annual accuracy verification of glucose meter (simultaneous fasting glucose meter/lab comparison within 20%).

* Blood glucose test strips are a Pharmacare benefit for those holding a valid Certificate of Training in self-monitoring of blood glucose from a BC diabetes education centre.

### Lipid Profile

- Measure fasting lipid profile (TC, HDL-C, LDL-C, triglycerides) initially. If within target without therapy then consider rechecking q1-3 years as clinically indicated.
- In patients receiving lipid treatment measure lipids within 6 to 8 weeks of initiation or change of pharmacotherapy and every 6 to 8 months thereafter (CK and ALT are the recommended safety tests)
- Apolipoprotein B (ApoB) can be used in place of lipid profiles for ongoing monitoring of therapy.
- Lipid targets must relate to the calculated risk, individualized to each patient, of developing CHD – although the majority of diabetic patients are high risk (see Controversies in Care). To estimate the 10-year risk of CHD for patients with type 2 DM use the UK prospective diabetes (UKPDS) risk calculator or table, available at: www.dtu.ox.ac.uk/riskengine/

### Lipid Targets (LDL-C or ApoB) According to CHD Risk Category*

<table>
<thead>
<tr>
<th>Risk Category</th>
<th>LDL-C (mmol/L)</th>
<th>ApoB (g/L)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moderate risk (&lt;20% 10-year risk)</td>
<td>&lt;3.5</td>
<td>&lt;1.05</td>
</tr>
<tr>
<td>High risk (≥20% 10-year risk)</td>
<td>&lt;2.5</td>
<td>&lt;0.85</td>
</tr>
</tbody>
</table>

* LDL-C target of < 2.0 or ApoB < 0.8 (or a 50% LDL-C decrease from the baseline value) has been suggested by the new CCS guidelines\(^{10}\) for individuals in the moderate risk category with LDL-C > 3.5 or ApoB > 1.0. (See Controversies in Care).

### Cardiovascular Disease

- Consider low dose ASA (81-325 mg) for people with stable cardiovascular disease. The decision to prescribe antiplatelet therapy for primary prevention of CV events should be based on individual clinical judgement.\(^{11}\)
- Consider employing ACEI for any patient over 55 years of age, patients with hypertension or patients with confirmed albuminuria.\(^{12}\)

### Retinopathy

Early recognition and treatment of retinopathy can prevent blindness.
- Ensure patient receives dilated pupil retinal examination at diagnosis, then every one to two years or as indicated (annual referral to optometrist/ophthalmologist).

### Nephropathy

- Screen for macroscopic proteinuria & non-renal disease with urine dipstick.
- If protein-negative dipstick measure albumin/creatinine ratio (ACR): If ACR is equivocal, repeat collection; treat ACR if persistently above normal threshold.
- Measure SCr (lab will report eGFR) at least annually. See Chronic Kidney Disease – Identification, Evaluation and Management of Patients.
- Treatment may not normalize subsequent ACRs or eGFR.
- Stages of classic diabetic nephropathy according to ACR (mg/mmol):
  - Normal: M <2.0; F <2.8; Micro-albuminuria (equivocal): M 2-20; F 2.8-28
  - Overt Nephropathy: M >20; F >28

### Neuropathy

The best way to prevent diabetic neuropathy is to regularly monitor and manage blood glucose.
- Check annually for symptoms or findings such as peripheral anesthetic neuropathy or pain, or autonomic neuropathy e.g. erectile dysfunction, gastrointestinal disturbance, orthostatic hypotension.
- Include screening via monofilament during foot exam.
Foot Examination

- Examine feet annually, and more frequently for those at high risk (i.e. patients with anesthetic neuropathy).
- Encourage regular self-examination of feet.

Psychosocial Aspects of Diabetes

Challenging psychosocial factors affect many aspects of diabetes management and glycemic control.

- Screen for depression, anxiety and eating disorders. Treatment of these conditions may improve outcomes.  
- Cognitive behaviour therapy (CBT) based techniques such as stress management strategies and coping skills can be implemented to improve outcomes.

Vaccinations

- Annual influenza vaccination.
- Pneumococcal vaccination: A single re-vaccination is recommended if the patient is >65 and previous vaccination was more than 5 years ago.

Additional Practice Points

Type 1 DM

- Patients with type 1 diabetes should see an experienced DM care team at diagnosis and at least annually.
- Insulin use: Multiple (3-4) daily injections or the use of continuous subcutaneous insulin infusions (CSII) should be considered as part of an intensive diabetes management program.

Type 2 DM

- See Appendix B Management of Hyperglycemia in Type 2 Diabetes.
- In elderly people with type 2 DM:
  - Polypharmacy: review medication list periodically, particularly if the patient presents with depression, falls, cognitive impairment, perceptual difficulties, or urinary incontinence.
  - Sulfonylureas: (especially glyburide) use with caution because the risk of hypoglycemia increases with age. Generally initial doses can be half of those for younger people and increased more slowly.
  - Monitor for postural BP.

Controversies in Care: Glycemic control

Several large prospective randomized trials have been published that have raised questions about appropriate targets and interventions for glycemic control for sub-populations of people with diabetes.

In support of A1C reduction and clinical complication reduction:

- The DCCT Trial showed that intervention with insulin for a mean of 6.5 years in people with type 1 diabetes to lower A1C (7.3% vs. 9.1%) resulted in reduced retinopathy progression, proteinuria progression, and neuropathy progression. A ten-year follow-up study also showed a “legacy” effect of that earlier period of intervention with reduced cardiovascular disease, myocardial infarction and death.
- The UKPDS showed that intervention with metformin, sulfonylureas and/or insulin in patients with newly diagnosed type 2 diabetes for a median follow-up of ten years to lower A1C (7.0% vs. 7.9%) resulted in reduced microvascular disease (largely driven by reduced need for retinal photocoagulation). In particular metformin is uniquely effective in decreasing macrovascular outcomes. A ten-year follow-up study also showed a “legacy” effect of that earlier period of intervention with reduced microvascular disease, myocardial infarction and death from any cause.
- A recent meta-analysis appears to show that “more-intensive glycemic control affords a modest but significant cardiovascular benefit in the short-to-medium term…”

Studies with A1C reduction showing either no benefit for complication reduction or harm:

- The VADT trial enrolled 1791 US veterans with type 2 diabetes. Coronary artery disease prevalence was 40%. Glycemic targets were A1C <6.0% vs. <9.0% for insulin addition. Achieved A1C was 7.0% vs. 8.5%. Metformin, glibenclamide and rosiglitazone were oral agents. There was no difference in cardiovascular outcomes or death rate in the two groups and there was significantly higher rate of hypoglycemia in the intensive group.
The ACCORD study glycemic control arm examined a population of 10,251 people with type 2 diabetes at increased risk for cardiovascular complications on the basis of existing cardiovascular disease or risk factors. All patients received blood pressure and lipid lowering therapy. The glycemic targets were A1C <6.0% (intensive-therapy group) vs. 7.0-7.9% (standard-therapy group). Multiple agents were used to achieve the targets, with 77% of the intensive-therapy group receiving insulin and the majority of this group also using at least 3 classes of oral agents. The intensive-therapy group was terminated because of a statistically significant excess mortality compared to the standard-therapy group.21

The 2008 CDA Guidelines use a “single A1C target” of ≤7.0% to make it “easier to incorporate into clinical practice” but acknowledge that “clinical judgment is required to determine which people can reasonably and safely achieve these targets”.22 A1C lowering in type 1 DM and newly diagnosed type 2 DM is associated with reduced complications; however, in patients with existing or high risk for CVD there is no evidence that a stringent A1C (less than 6) has a benefit and there are increased side effects.

**Controversies in Care: Risk Calculation**

Some authorities suggest all patients with diabetes should be considered at high risk (20% ten year risk for a CAD event or 2% per year) for coronary artery disease.23 This recommendation is often based on an article by Haffner et al. which showed equal risk for death from coronary artery disease in a cohort of diabetic patients who had not had an MI and of non-diabetic patients who had a previous MI.24 But a recent meta-analysis by Bulugahapityia et al., which included the Haffner data, demonstrated significantly lower risk of CAD for patients with diabetes compared to those with a prior MI.25

Recent CDA guidelines recommended that all men with diabetes over age 45 and all women with diabetes over age 50 (and some under those age cut-offs) be considered at high risk for CAD.26 This recommendation was based on an article by Booth et al. Booth demonstrated that the average man with diabetes in a cohort (Ontario, Canada) became high risk at the age of 49 and the average woman with diabetes at age 56.27

The alternative to such broad, population-based, definitions of “high risk” is an individual calculation using a risk calculator (e.g., [UKPDS risk calculator](https://www.ukpds.org.uk/pt/index.html) and [DiabetesPHD (personal health decisions)](http://www.diabetesphd.com/)). Many other risk calculators also exist. Risk calculators differ in terms of ease of use and data entered. They may over- or under-estimate a patient’s true risk. But, risk calculators provide the clinician the ability to input a variety of patient specific characteristics (more than just age and gender) in order to estimate a patient’s risk for a variety of diabetes-related complications.

**Controversies in Care: SMBG**

SMBG is a commonly recommended medical technology. On a population basis, the majority of glucose test strip use is by people with type 2 diabetes who do not use insulin. A recent meta-analysis of this group showed a slightly lower A1C (-0.25%) in patients who perform SMBG vs no testing.28 The review found “sparse and inconsistent data” to suggest that SMBG conferred benefit in terms of Health-Related Quality of Life, patient satisfaction, long-term complications and mortality. When economic factors were also reviewed, SMBG was found to be relatively cost-ineffective and routine self-testing of blood glucose was not recommended in this population. The review suggested that the frequency of SMBG be “individualized” in certain groups of people, e.g patients with diabetes who use insulin, patients with gestational diabetes, or those who have special considerations i.e adjustment of medication regimen.29

**Controversies in Care: Lipid Targets**

The issue of lipid targets for patients with diabetes is complicated and often debated in the context of CV risk assessment and clinical trial results. There are several algorithms for the CV risk: UKPDS, Framingham, Procam, Reynold etc. Depending on which one is used, the predicted risk may be remarkably different. The results from prospective, double blind, placebo-controlled statin trials in patients with diabetes show significant benefits of the treatment. Thus the current expert opinion from the Canadian Cardiovascular Society (CCS) and American Diabetes Association (ADA) guidelines state that “most patients with diabetes will benefit from treatment with statins to the high risk LDL-C or ApoB target”.30,31 It is hoped that these numbers guide treatment rather than define an absolute target that must be achieved.
References

List of Abbreviations and Acronyms

A1C  glycosylated hemoglobin, formerly known as HbA1c
ACEI  angiotensin-converting enzyme inhibitors
ApoB  apolipoprotein B
ARB  angiotensin II receptor blocker
ASA  acetylsalicylic acid
BID  to be taken twice a day
BMI  body mass index
BP  blood pressure
CHD  coronary heart disease
CHF  congestive heart failure
eCPS  Electronic Compendium of Pharmaceuticals and Specialties
CSII  continuous subcutaneous insulin infusions
CVD  cardiovascular disease
DM  diabetes mellitus
ECG  electrocardiogram
eGFR  estimated glomerular filtration rate
FPG  fasting plasma glucose
HDL-C  high-density lipoprotein cholesterol
IFG  impaired fasting glucose
IGT  impaired glucose tolerance
LDL-C  low-density lipoprotein cholesterol
OD  to be taken once a day
PG  plasma glucose
SMBG  self-monitoring of blood glucose
TG  triglycerides
TZD  thiazolidinedione
ULN  upper limit of normal

DISCLAIMER
The Clinical Practice Guidelines (the “Guidelines”) have been developed by the Guidelines and Protocols Advisory Committee on behalf of the Medical Services Commission. The Guidelines are intended to give an understanding of a clinical problem, and outline one or more preferred approaches to the investigation and management of the problem. The Guidelines are not intended as a substitute for the advice or professional judgment of a health care professional, nor are they intended to be the only approach to the management of clinical problems.
**Appendix A: Screening Algorithm for Type 2 Diabetes in Adults**

Screen every 3 years in individuals ≥40 years of age
Screen earlier and/or more frequently in people with additional risk factors for diabetes (see risk factors)

- **FPG**
  - <5.6 mmol/L
  - 5.6 – 6.0 mmol/L
  - 6.1 – 6.9 mmol/L
  - ≥7.0 mmol/L

<table>
<thead>
<tr>
<th>&lt;5.6 mmol/L</th>
<th>5.6 – 6.0 mmol/L</th>
<th>6.1 – 6.9 mmol/L</th>
<th>≥7.0 mmol/L</th>
</tr>
</thead>
<tbody>
<tr>
<td>If no risk factors - re-screen more often</td>
<td>If ≥1 risk factors consider: 75 g OGTT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **75 g OGTT**
  - Fasting value: 6.1 – 6.9 mmol/L
  - 2-h value: 7.8-11.0 mmol/L
  - Fasting value: ≥7.0 mmol/L
  - 2-h value: >11 mmol/L

<table>
<thead>
<tr>
<th>Normal† - re-screen as recommended</th>
<th>Pre-diabetes§</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Diabetes</strong>§</td>
<td></td>
</tr>
</tbody>
</table>

† Adapted from: Canadian Diabetes Association Clinical Practice Guidelines Expert Committee; Screening for Type 1 and Type 2 Diabetes. Can J Diabetes 2008;32 (Supp.1): S15.

‡ Isolated IGT: fasting value <6.1 mmol/L and 2-h value 7.8-11.0 mmol/L
Isolated IFG: fasting value 6.1 - 6.9 mmol/L and 2-h value <7.8 mmol/L
IFG and IGT: fasting value 6.1 – 6.9 mmol/L and 2-h value 7.8-11.0 mmol/L

‡‡ If, despite a normal fasting value, a 75 g OGTT is subsequently performed and the 2hPG value is 7.8- 11.0 mmol/L, a diagnosis of isolated IGT is made.

§ The term “prediabetes” refers to IFG and/or IGT. These individuals are at risk of developing DM, should be monitored regularly, and benefit from CVD risk factor modification.

§§ A confirmatory laboratory glucose test (either a FPG, casual PG or a 2hPG in a 75 g OGTT) must be done on another day in all cases in the absence of unequivocal hyperglycemia accompanied by acute metabolic decompensation.

**Key:** FPG= fasting blood glucose; 75g OGTT= 75 g oral glucose tolerance test; 2hPG= 2-hour plasma glucose; CVD= cardiovascular disease; IFG= impaired fasting glucose; IGT= impaired glucose tolerance; PG= plasma glucose.

Appendix D: Insulin Therapeutic Considerations and Availability

### Therapeutic Considerations

**Type 1 diabetes:**
Intensive treatment e.g. basal-bolus regimens (e.g. multiple daily injections or continuous subcutaneous insulin infusion) are the insulin regimen of choice.

1. **Basal insulin:** insulin NPH once or twice daily as first line in addition to bolus insulin. If severe hypoglycemia try **long-acting insulin analogues** (glargine once daily, detemir once daily or bid).
2. **Bolus insulin:** either regular human insulin or rapid-acting insulin analogues bid or tid with meals as first line.
   a. **Regular human insulin** if cost is an issue.
   b. **Rapid-acting insulin analogues** if:
      - flexibility needed (given just before or within 15 minutes of starting meal),
      - significant hypoglycemia with regular human insulin,
      - concern for hypoglycemia.

**Type 2 diabetes:**

- Potentially greatest A1C reduction and no maximal dose.
- Increased risk of weight gain (∼2-4 kg) relative to sulfonylureas and metformin.
- Associated with hypoglycemia (long-acting analogues <NPH; Rapid analogues <regular insulin).
- Beneficial effects on triglyceride and HDL cholesterol.
- Avoid insulin in patients on thiazolidinedione (increased heart failure, weight gain and edema). Stop therapy with thiazolidinedione before adding insulin.

**1. Basal insulin:** consider adding bedtime insulin NPH as first line to daytime oral antidiabetic.
   - Starting dose: 10 units basal insulin at qhs, increase by 1 unit/day until achieving FPG ≤ 5.5 mmol/L.
   - If severe hypoglycemia to insulin NPH try **long-acting insulin analogues**.

**2. Bolus insulin:** consider intensive insulin with **regular human insulin** if basal insulin regimen fails to attain glycemic targets.
   - If severe hypoglycemia to regular human insulin try **rapid-acting insulin analogue**.

What is Prediabetes?

Prediabetes refers to having blood sugar levels that are higher than normal, but not high enough to be considered diabetic. Pre-diabetes is also called impaired glucose tolerance or impaired fasting glucose. Pre-diabetes is treated by lowering high blood sugar levels through exercise and by following a healthy meal plan.

For support see the resources section!

I have type 2 Diabetes – what can I do?

**Education:** Diabetes education is an important first step. See the resources section and develop a monitoring plan with your care provider to help track your blood sugar, cholesterol, blood pressure etc.

**Physical Activity:** Regular physical activity helps your body lower blood sugar levels, promotes weight loss, reduces stress and enhances overall fitness.

**Nutrition:** What, when, and how much you eat all play an important role in regulating blood sugar levels (see Glycemic index section).

**Blood Pressure:** High blood pressure can lead to eye disease, heart disease, stroke and kidney disease, so people with diabetes should try to maintain a blood pressure level below 130/80. To do this, you may need to change your eating and physical activity habits and/or take medication.

**Medication:** Besides activity and healthy eating, your doctor may prescribe medications and/or insulin.

What are the symptoms of Hypoglycemia?

- Dizziness, shakiness
- Sweating
- Weakness, drowsiness
- Intense hunger
- Headache
- Looking pale
- Sudden moodiness or behaviour changes (e.g. crying for no reason)
- Confusion
- Faster heart rate
- Tingling or numbness on your tongue or lips

If you experience these symptoms, check your blood sugar levels right away. If you don’t have your meter with you, play it safe and treat the symptoms anyway.

How do I treat hypoglycemia?

Eat or drink a fast-acting carbohydrate. The best choice is 15g of glucose or sucrose in the form of tablet or solution. If this is not available, try:

- 15ml (3 tsp) or 3 packets of table sugar dissolved in water
- 175ml (3/4 cup) of juice or regular soft drink
- 6 Life Savers® (1=2.5g of carbohydrate)
- 15ml (1 tbsp) of honey

Hypoglycemia happens to everyone with diabetes from time to time, even if you’re doing all you can to manage your diabetes. But if you’re having frequent episodes, it may mean your medication needs to be adjusted. Be sure to talk to your doctor and always wear your MedicAlert® identification.

Glycemic Index and Diabetes

The glycemic index (GI) is a system of grouping carbohydrate foods (carbs) based on how they affect your blood sugar levels. See the reference in this guide. Carbohydrates are the sugars and starches in the foods you eat. This is what your body uses for energy. Carbohydrates are found in grains and cereals, dried peas and beans, fruits and vegetables, milk and yogurt, as well as sugar and sugar-containing foods. Some carbohydrate foods are broken down and absorbed quickly while others are broken down and absorbed more slowly.
What are the benefits of using low GI foods?

- Can help to ‘even out’ the highs and lows (more stable blood sugar)
- Can lower triglycerides & ‘bad’ cholesterol and may help your ‘good’ cholesterol
- May help you feel full for longer & eat less at the next meal or snack

Helpful Tips:
Introduce low GI foods gradually - include at least one low GI food at each meal and monitor their effects on your blood sugar level. A high GI food & a low GI food make an intermediate GI meal.

Eat a variety of foods each day - Do NOT exclude foods based only on the GI value. High GI foods are still good sources of energy. Monitor the amount of carbohydrates eaten at each meal and snack.

- Eating large amounts of low GI foods can still make blood glucose levels too high
- Checking your blood glucose before & after meals is the best way to see if you are eating the right amount of type of carbohydrate
- Aim to keep your blood glucose between 5 & 10 one to two hours after meals
- Choose foods from the low GI group more often.
- Monitor the amount of carbohydrates eaten at each meal and snack.

Low GI Menu Suggestions
See below for meal suggestion and the brief GI index reference guide.

Breakfast
- Use a low GI bread or cereal (see GI reference guide). Add some low fat milk or yogurt and fruit to kick start the day.
- Old fashioned oats with low fat milk and raisins.
- Poached egg on multigrain toast with a fresh orange.

Lunch Break
- Soups and sandwiches with a green salad or raw vegetables offer quick lunch solutions all year round.
- Sandwich made with a sprouted grain bread. Fill with tuna, salmon, lean meat or chicken; add lettuce, sprouts tomatoes &/or cucumber.
- Pumpernickel bagel topped with light cream cheese & smoked salmon.

Supper suggestions
- Base your meal on a low GI starch. Add plenty of vegetables & keep protein portions moderate
- Meatloaf made with rolled oats and grated vegetables (carrots & zucchini). Serve with new potatoes.
- Vegetable lasagna made with low fat cheese.

Snacktime!
To keep your energy up between meals, try the following nutritious snacks:

- Low fat milk & low GI cereal.
- Low fat yogurt and fresh fruit.
- Low fat milk & oatmeal cookies.
- Oat or oat bran muffins & fruit.
- Whole wheat pita and hummus.
- Stoned wheat thins or Ryvita™ with low fat cheese.

Resources:
See www.HealthLinkBC.ca or the handbook that was delivered to households throughout the province or call 8-1-1 (TTY call 7-1-1). Visit the Canadian Diabetes Association at www.diabetes.ca or call toll free 1 800 226-8464 for further information. See Canada’s Food Guide for healthy eating tips, available in multiple languages.

See www.ActNowBC.ca and Canada’s Physical Activity Guide for tips on healthy eating and lifestyle. For assistance to quit smoking, see www.quitnow.ca or call 1 877 455-2233 (toll free in BC) to obtain self help materials.

Your family doctor may refer you to a local Diabetes Education Clinic. These clinics have courses and information to help you manage your diabetes. In addition to your family physician, in some parts of the province there are a number of other professionals who may assist you in the management of diabetes (A Diabetes Team).

Members of your diabetes team may include: Nurse educators, Nutritionists &/or specialists (example eye &/or foot doctors), Community programs etc. Your doctor will provide a referral if necessary.
